Keywords: Multi-robots coordination Reinforcement learning Robot control

1. Introduction

Coordinated manipulation of multi-robots has attracted researchers' attention as it provides better rigidity and feasibility compared to manipulation of a single robot, yet it brings along challenging control problems [1]. Different from control of a single robot manipulator, a coordination scheme is needed to avoid possible disagreement between multi-robots, which will lead to undesired results, e.g., large internal forces [2]. Typical coordination control schemes include hybrid position/force control and leader-follower control [3]. Hybrid position/force control considers the position of the manipulated object to be in a certain workspace, and the internal force to be within a small range around the origin. In comparison, the leader-follower method introduces a leader individual, which is followed by other manipulators. Regrading these two coordination control schemes, while the former requires the separation of directions for position and force controls [4], the latter needs multi-robots to communicate with each other through different interfaces. Enlightened by the idea of optimal control, i.e., to achieve the trajectory tracking and simultaneously to penalize the control effort, we propose a coordination scheme in this paper to avoid limitations in existing methods. In particular, when manipulating a common object by multi-robots, each individual aims to track a prescribed trajectory while it complies to others by penalizing its own control effort.

ABSTRACT

In this paper, coordination control is investigated for multi-robots to manipulate an object with a common desired trajectory. Both trajectory tracking and control input minimization are considered for each individual robot manipulator, such that possible disagreement between different manipulators can be handled. Reinforcement learning is employed to cope with the problem of unknown dynamics of both robots and the manipulated object. It is rigorously proven that the proposed method guarantees the coordination control of the multi-robots system under study. The validity of the proposed method is verified through simulation studies.

This will lead to an optimization-like problem which cannot be handled by conventional optimal control, e.g., linear quadratic regulator (LQR) [5], due to uncertain and nonlinear system dynamics. In the literature, reinforcement learning, also known as adaptive dynamic programming, has been extensively studied in the control community to address this issue [6,7].

The idea of reinforcement learning is inspired by the phenomena that human beings and other animals always learn from experience through reward and punishment results for survival and growth [8–11]. In particular, biological experiments show that the dopamine neurotransmitter acts as a reinforcement signal which favors learning at the neuron level [12]. Based on reinforcement learning, a control signal can be generated for an agent to interact with unknown environments. Typically, a cost function or a reward function is defined to describe the control objective, and a control scheme is developed to minimize/maximize the defined cost/reward function [13]. Therefore, a reinforcement learning control can be developed in the form of a composition of two parts: a critic network and an actor network. A critic network is developed to approximate the cost function, while an actor network plays a role to minimize the cost function. Reinforcement learning control has been developed in both continuous-time and discrete-time domains. In [14], a reinforcement learning control has been proposed for systems in continuous time and space. In [15], a state observer is introduced to estimate the future state for the design of adaptive dynamic programming for unknown nonlinear continuous-time systems. In [16], a discrete-time reinforcement learning control is proposed with Lyapunov stability analysis. In [17], optimal control is proposed for unknown

nonaffine discrete-time systems by employing adaptive dynamic programming. Reinforcement learning control has also been investigated in control of robots. In [18], a natural actor-critic algorithm is adopted for the learning of proper impedance for robots in interacting with unknown environments. In [19], the algorithm of policy improvement with path integrals is integrated with reinforcement learning to achieve variable impedance control. In [20], impedance adaptation for robot control is developed based on adaptive dynamic programming proposed in [21]. Literature reviews of reinforcement learning can be found in [22,23], which introduce the use of reinforcement learning in feedback control and state open challenges of developing a reinforcement learning control.

Based on the above discussions, in this paper, we will introduce a reinforcement learning control for coordinated manipulation of multi-robots. First, a cost function is defined to describe the tracking objective of each individual robot manipulator and its compliance to others. Then, the coordination problem of multirobots will be transformed to an optimization-like problem. A reinforcement learning control will be designed to minimize the defined cost function, in the presence of unknown system dynamics. Eventually, through Lyapunov stability analysis, the performance of the proposed method will be discussed in detail.

The contributions of this paper are highlighted as follows:

- (i) the problem of multi-robots coordination is formulated such that both the tracking objective of each individual robot manipulator and its compliance to others are described, with neither the separation of task spaces nor extra communication interfaces;
- (ii) system dynamics are transformed to a general model similar to that of a single robot manipulator for the feasibility of control design; and
- (iii) a reinforcement learning control is developed subject to unknown dynamics of robot manipulators and object, which guarantee the coordination control of multi-robots.

The rest of the paper is organized as follows. In Section 2, the problem of coordination control under study is formulated. In Section 3, the transformation of system dynamics and design of a reinforcement learning control are detailed, followed by the rigorous performance analysis. In Section 4, the validity of the proposed method is verified through simulation studies. Section 5 concludes this paper.

2. Problem formulation

2.1. System description

The system under study includes n individual robot manipulators and a rigid object, where the object is tightly grasped by the end-effector of each robot manipulator. It is assumed that there is no relative motion between the robot manipulators and object.

The dynamics of the object in the task space are described as

$$m_{o}\ddot{p} - m_{o}g = f_{o}$$

$$I_{o}\dot{\omega} + \omega \times I_{o}\omega = \tau_{o}$$
(1)

where m_o and I_o are the mass and inertia matrix of the manipulated object, p and ω are the position and angular velocity of the object, respectively, f_o and τ_o are the force and torque applied to the mass center of the object, respectively, and g is the gravitational acceleration.

Define $x_o = [p^T, \theta^T]^T$ where $\dot{\theta} = \omega$, and we have $\dot{x}_o = [\dot{p}^T, \omega^T]^T$. Then, the dynamics of the object can be rewritten in the following form [24]:

$$M_o \ddot{x}_o + C_o (\dot{x}_o) \dot{x}_o + G_o = F_o \tag{2}$$

where
$$M_o = \begin{bmatrix} m_o I & 0 \\ 0 & I_o \end{bmatrix} \in \mathbb{R}^{m \times m}$$
, $C_o(\dot{x}_o)\dot{x}_o = \begin{bmatrix} 0 \\ \omega \times I_o \omega \end{bmatrix} \in \mathbb{R}^m$, $G_o = \begin{bmatrix} -m_o g \\ 0 \end{bmatrix} \in \mathbb{R}^m$, and $F_o(t) = \begin{bmatrix} f_o \\ \tau_o \end{bmatrix} \in \mathbb{R}^m$.

Property 1. The matrix $C_o(\dot{x}_o)$ is skew-symmetric, i.e., $\varrho^T C_o(\dot{x}_o) \varrho = 0$, for $\forall \varrho \in \mathbb{R}^m$.

The forward kinematics of the *i*-th robot manipulator is described by $x_i = \varphi_i(q_i)$, where $x_i(t) \in \mathbb{R}^{m_i}$ and $q_i \in \mathbb{R}^{m_i}$ are positions/orientations in the Cartesian space and joint coordinates in the joint space, respectively. Differentiating $x_i = \phi(q_i)$ with respect to time results in $\dot{x}_i = J_{r,i}(q_i)\dot{q}_i$, where $J_{r,i}(q_i) \in \mathbb{R}^{m_i \times m_i}$ is the Jacobian matrix for the *i*-th robot manipulator. Besides, $J_i(x_o)$ is the Jacobian matrix which describes the kinematic relationship between the mass center of the object and the end-effector of the *i*-th robot manipulator.

Assumption 1. The Jacobian matrices $J_{r,i}(q_i)$ and $J_i(x_o)$ are nonsingular in a finite workspace.

The dynamics of the *i*-th robot manipulator in the joint space are

$$M_{r,i}(q_i)\ddot{q}_i + C_{r,i}(q_i, \dot{q}_i)\dot{q}_i + G_{r,i}(q_i) + J_{r,i}^T(q_i)F_i = u_{r,i}, \quad i = 1, 2, 3, ..., n$$
(3)

where $M_{r,i}(q_i) \in \mathbb{R}^{m_i \times m_i}$ is the inertia matrix, $C_{r,i}(q_i, \dot{q}_i) \dot{q}_i \in \mathbb{R}^{m_i}$ denotes the Coriolis and Centrifugal force, $G_{r,i}(q_i) \in \mathbb{R}^{m_i}$ is the gravitational force, F_i denotes the force exerted on the object by the end-effector of the *i*-th robot manipulator at the interaction point, and $u_{r,i} \in \mathbb{R}^{m_i}$ is the control input.

By considering the Jacobian matrix $J_{r,i}(q_i)$, the dynamics of the *i*-th robot manipulator can be described in the Cartesian space as below:

$$M_i(q_i)\ddot{x}_i + C_i(q_i, \dot{q}_i)\dot{x}_i + G_i(q_i) + F_i = u_i, \quad i = 1, 2, 3, ..., n$$
(4)

where

$$M_{i}(q_{i}) = J_{r,i}^{-T}(q_{i})M_{r,i}(q_{i})J_{r,i}^{-1}(q_{i})$$

$$C_{i}(q_{i}, \dot{q}_{i}) = J_{r,i}^{-T}(q_{i})(C_{r,i}(q_{i}, \dot{q}_{i}) - M_{r,i}(q_{i}, \dot{q}_{i})J_{r,i}^{-1}(q_{i})\dot{J}_{r,i}(q_{i}))J_{r,i}^{-1}(q_{i})$$

$$G_{i}(q_{i}) = J_{r,i}^{-T}(q_{i})G_{r,i}(q_{i}), \quad u_{i} = J_{r,i}^{-T}(q_{i})u_{r,i}$$
(5)

Property 2 (*Ge et al.* [25]). The matrix $M_i(q_i)$ is symmetric and positive definite.

Property 3 (*Ge et al.* [25]). The matrix $\dot{M}_i(q_i) - 2C_i(q_i, \dot{q}_i)$ is skewsymmetric if $C_i(q_i, \dot{q}_i)$ is in Christoffel form, i.e. $\varrho^T(\dot{M}_i(q_i) - 2C_i(q_i, \dot{q}_i))\varrho = 0$, for $\forall \varrho \in \mathbb{R}^{m_i}$.

The control objective of this work is to let the object move along a desired trajectory x_d while minimizing the control efforts of all robot manipulators. In particular, we define the following cost function:

$$\Gamma(t) = \int_0^\infty c(s) \,\mathrm{d}s \tag{6}$$

where c(t) is an instant cost function defined as

$$c(t) = (x_o - x_d)^T Q_1 (x_o - x_d) + \dot{x}_o^T Q_2 \dot{x}_o + \sum_{i=1}^n u_{r,i}^T R_i u_{r,i}$$
(7)

where $Q_1 \ge 0$, $Q_2 \ge 0$, and $R_i > 0$.

Remark 1. The rule of thumb to choose Q_1 and R_i is as follows: a larger value for Q_1 indicates that a more accurate tracking performance is expected, a larger value for Q_2 indicates that a smoother motion is desirable, and a larger value for R_i indicates that the load of the *i*-th robot manipulator is expected to be

smaller. For example, it is usual to allocate a larger load to a "stronger" robot manipulator (with larger mass and inertia of moment), so R_i should be given a smaller value for this robot manipulator.

2.2. Preliminary

For approximation of a continuous function $h(Z) : \mathbb{R}^r \to \mathbb{R}$, the following Radial Function Basis (RBF) Neural Networks (NN) are used [26]:

$$h(Z) = W^{*T}S(Z) + \epsilon \tag{8}$$

where $Z \in \mathbb{R}^r$ is the NN input vector, W^* is the ideal NN weight, and ϵ is the approximation error under the ideal NN weight. $S(Z) = [s_1(Z), ..., s_l(Z)]$ is a vector where $s_i(Z)$ is chosen as the Gaussian function for i = 1, 2, ..., l, which is expressed as

$$s_i(Z) = \exp\left[\frac{-(Z-\mu_i)^T (Z-\mu_i)}{\eta_i^2}\right]$$
(9)

where μ_i is the designed center for the *i*-th input element of the NN, and η_i the width of the Gaussian function.

Lemma 1 (Ge and Wang [27]). Consider a positive function given by

$$V(t) = \frac{1}{2}e^{T}(t)\Lambda(t)e(t) + \frac{1}{2}\tilde{W}^{T}(t)\Gamma^{-1}(t)\tilde{W}(t)$$
(10)

where $e(t) = \xi(t) - \xi^*(t)$ and $\tilde{W}(t) = \hat{W}(t) - W^*$, and $\Lambda(t) = \Lambda^T(t) > 0$ and $\Gamma(t) = \Gamma^T(t) > 0$ are dimensionally compatible matrices. If the following inequality holds:

$$\dot{V}(t) \le \rho V(t) + \kappa \tag{11}$$

where ρ and κ are positive constants, then, given any initial compact set defined by

$$\Omega_0 = \left\{ \xi(0), \xi^*(0), \hat{W}(0) | \xi(0), \hat{W}(0) \text{ finite}, \xi^*(0) \in \Omega^* \right\}$$
(12)

we can conclude that the states and weights will eventually converge to the compact sets defined by

$$\Omega_{s} = \left\{ \xi(t), \hat{W}(t) | \lim_{t \to \infty} \| e(t) \| = \mu_{e}^{*}, \lim_{t \to \infty} \| \tilde{W} \| = \mu_{\tilde{W}}^{*} \right\}$$
(13)

where constants

$$\mu_e^* = \sqrt{\frac{2\kappa}{\rho\lambda_{\rm Amin}}}$$

$$\mu_{\tilde{W}}^* = \sqrt{\frac{2\kappa}{\rho\lambda_{\rm Fmin}}}$$
(14)

with $\lambda_{A\min} = \min_{\nu \in [0,t]} \lambda_{\min}(\Lambda(\nu))$, and $\lambda_{\Gamma\min} = \min_{\nu \in [0,t]} \lambda_{\min}(\Gamma^{-1}(\nu))$.

3. Control design

3.1. System transformation

By applying the virtual work principle, we can obtain the relationship between the end-effector forces F_i with the force applied to the mass center of the object F_o . In particular, we have

$$(-F_1)^T \delta x_1 + (-F_2)^T \delta x_2 + \dots + (-F_n)^T \delta x_n + F_0^T \delta x_0 = 0$$
(15)

Since $\delta x_i = J_i(x_o) \delta x_o$, we obtain

$$F_{o} = \sum_{i=1}^{n} J_{i}^{T}(x_{o})F_{i}$$
(16)

Since $\ddot{x}_i = \dot{J}_i(x_0)\dot{x}_0 + J_i(x_0)\ddot{x}_0$, the dynamics of the *i*-th robot can be

redescribed as

$$M_{i}(q_{i})J_{i}(x_{o})\ddot{x}_{o} + \left(M_{i}(q_{i})\dot{J}_{i}(x_{o}) + C_{i}(q_{i},\dot{q}_{i})J_{i}(x_{o})\right)\dot{x}_{o} + G_{i}(q_{i}) + F_{i} = u_{i}$$
(17)

Multiplying both sides of the above equation by $J_i^T(x_o)$, we have

$$J_{i}^{T}(x_{o})M_{i}(q_{i})J_{i}(x_{o})\ddot{x}_{o} + J_{i}^{T}(x_{o})\left(M_{i}(q_{i})\dot{J}_{i}(x_{o}) + C_{i}(q_{i},\dot{q}_{i})J_{i}(x_{o})\right)\dot{x}_{o} + J_{i}^{T}(x_{o})G_{i}(q_{i}) + J_{i}^{T}(x_{o})F_{i} = J_{i}^{T}(x_{o})u_{i}$$
(18)

By adding the above dynamics of all the robot manipulators together, we obtain the following combined dynamics:

$$\sum_{i=1}^{n} J_{i}^{T}(x_{o}) M_{i}(q_{i}) J_{i}(x_{o}) \ddot{x}_{o} + \sum_{i=1}^{n} J_{i}^{T}(x_{o}) \Big(M_{i}(q_{i}) \dot{J}_{i}(x_{o}) + C_{i}(q_{i}, \dot{q}_{i}) J_{i}(x_{o}) \Big) \dot{x}_{o}$$
$$+ \sum_{i=1}^{n} J_{i}^{T}(x_{o}) G_{i}(q_{i}) + \sum_{i=1}^{n} J_{i}^{T}(x_{o}) F_{i} = \sum_{i=1}^{n} J_{i}^{T}(x_{o}) u_{i}$$
(19)

Considering Eq. (16) and substituting the dynamics of the object, i.e., Eq. (2), into Eq. (19), we obtain the model of the overall system as below:

$$\left(\sum_{i=1}^{n} J_{i}^{T}(x_{o}) M_{i}(q_{i}) J_{i}(x_{o}) + M_{o} \right) \ddot{x}_{o} + \left(\sum_{i=1}^{n} J_{i}^{T}(x_{o}) \left(M_{i}(q_{i}) \dot{J}_{i}(x_{o}) + C_{i}(q_{i}, \dot{q}_{i}) J_{i}(x_{o}) \right) + C_{o}(\dot{x}_{o}) \right) \dot{x}_{o} + \left(\sum_{i=1}^{n} J_{i}^{T}(x_{o}) G_{i}(q_{i}) + G_{o} \right) = \sum_{i=1}^{n} J_{i}^{T}(x_{o}) u_{i}$$

$$(20)$$

By defining

$$M(q_{i}, x_{o}) = \sum_{i=1}^{n} J_{i}^{T}(x_{o})M_{i}(q_{i})J_{i}(x_{o}) + M_{o}$$

$$C(q_{i}, \dot{q}_{i}, x_{o}, \dot{x}_{o}) = \sum_{i=1}^{n} J_{i}^{T}(x_{o}) \left(M_{i}(q_{i})\dot{J}_{i}(x_{o}) + C_{i}(q_{i}, \dot{q}_{i})J_{i}(x_{o})\right) + C_{o}(\dot{x}_{o})$$

$$G(q_{i}, x_{o}) = \sum_{i=1}^{n} J_{i}^{T}(x_{o})G_{i}(q_{i}) + G_{o}$$

$$u = \sum_{i=1}^{n} J_{i}^{T}(x_{o})u_{i}$$
(21)

the above system model can be rewritten as

$$M(q_i, x_o)\ddot{x}_o + C(q_i, \dot{q}_i, x_o, \dot{x}_o)\dot{x}_o + G(q_i, x_o, \dot{x}_o) = u$$
(22)

According to Properties 1–3, we immediately obtain the following properties for the combined system (22).

Property 4. The matrix $M(q_i, x_o)$ is symmetric and positive definite.

Property 5. The matrix $\dot{M}(q_i, x_o) - 2C(q_i, \dot{q}_i, x_o, \dot{x}_o)$ is skew-symmetric, i.e. $\varrho^T(\dot{M}(q_i, x_o) - 2C(q_i, \dot{q}_i, x_o, \dot{x}_o))\varrho = 0$, for $\forall \varrho \in \mathbb{R}^m$.

$$\begin{aligned} & \text{Proof.} \\ & \dot{M}(q_i, x_o) - 2C(q_i, \dot{q}_i, x_o, \dot{x}_o) \\ &= \sum_{i=1}^n (2J_i^T(x_o) M_i(q_i) \dot{J}_i(x_o) + J_i^T(x_o) \dot{M}_i(q_i) J_i(x_o)) + \dot{M}_o \\ &- \sum_{i=1}^n 2J_i^T(x_o) (M_i(q_i) \dot{J}_i(x_o) + C_i(q_i, \dot{q}_i) J_i(x_o)) - 2C_o(\dot{x}_o) \\ &= \sum_{i=1}^n J_i^T(x_o) (\dot{M}_i(q_i) - 2C_i(q_i, \dot{q}_i)) J_i(x_o) - 2C_o(\dot{x}_o) \end{aligned}$$
(23)

Recalling Properties 3 and 1 of robot manipulators and object dynamics, we can obtain

$$\begin{aligned} x_o^I(M(q_i, x_o) - 2C(q_i, \dot{q}_i, x_o, \dot{x}_o))x_o \\ &= \sum_{i=1}^n (J_i(x_o)x_o)^T (\dot{M}_i(q_i) - 2C_i(q_i, \dot{q}_i))J_i(x_o)x_o + x_o^T (\dot{M}_o - 2C_o(\dot{x}_o))x_o \end{aligned}$$

Ϋ́1

$$=\sum_{i=1}^{n} x_{i}^{T} (\dot{M}_{i}(q_{i}) - 2C_{i}(q_{i}, \dot{q}_{i}))x_{i} - 2x_{o}^{T}C_{o}(\dot{x}_{o})x_{o} = 0$$
(24)

for $\forall x_0 \in \mathbb{R}^m$. Replacing x_0 by ρ completes the proof.

. .

Similarly as in [20], we consider the desired trajectory generated by the following system:

$$\begin{cases} \dot{z} = Uz \\ x_d = Yz \end{cases}$$

where $z \in R^m$ is an auxiliary variable, $U \in R^{m \times m}$ and $Y \in R^{m \times m}$ are known matrices, and (U,Y) is observable. Then, the instant cost function defined in (7) becomes

$$c(t) = \begin{bmatrix} x_o^T & x_d^T \end{bmatrix} \begin{bmatrix} Q_1 & -Q_1 \\ -Q_1 & Q_1 \end{bmatrix} \begin{bmatrix} x_o \\ x_d \end{bmatrix} + \dot{x}_o^T Q_2 \dot{x}_o + \sum_{i=1}^n u_{r,i}^T R_i u_{r,i}$$
$$= \begin{bmatrix} x_o^T & z^T \end{bmatrix} \begin{bmatrix} Q_1 & -Q_1 Y \\ -Y^T Q_1 & Y^T Q_1 Y \end{bmatrix} \begin{bmatrix} x_o \\ z \end{bmatrix} + \dot{x}_o^T Q_2 \dot{x}_o + \sum_{i=1}^n u_{r,i}^T R_i u_{r,i}$$
(25)

Denote $\xi = [x_0^T, z^T, \dot{x}_0^T]^T$, $u' = [u_1^T, u_2^T, ..., u_n^T]^T$, $R' = \text{diag}[(J_{r,i}(q_i)$ $R_i J_{r,i}^T(q_i)$ for i = 1, 2, ..., n, and

$$Q = \begin{bmatrix} Q_1 & -Q_1 Y & 0\\ -Y^T Q_1 & Y^T Q_1 Y & 0\\ 0 & 0 & Q_2 \end{bmatrix}$$
(26)

Then, we obtain

$$c(t) = \xi^T Q \xi + u'^T R' u' \tag{27}$$

Denote $J' = [J_1^T, J_2^T, ..., J_n^T]^T$. From the definition of *u* in (21), we know that $u = J^{T}u^{T}$. Therefore, the above instant cost function is finally written as

$$c(t) = \xi^T Q \xi + u^T R u \tag{28}$$

where $R = I^{\dagger} R' I^{\dagger T}$ with I^{\dagger} being the pseudoinverse of I'.

Following the transformation in this subsection, the coupled dynamics of multi-robot manipulators and object are described in a unified form, i.e., Eq. (22). Then, it becomes straightforward to design a control for such a general system to minimize the cost function (6). Since $M(q_i, x_0)$, $C(q_i, \dot{q}_i, x_0, \dot{x}_0)$, and $G(q_i, x_0)$ are unknown and typically nonlinear due to the involvement of robot and object dynamics, we develop reinforcement learning for the control design of system (22), as detailed in the following subsection.

3.2. Reinforcement learning

۵E

First, a critic network is used to approximate the cost function at current state, i.e.,

$$\begin{aligned}
\Upsilon(t) &= W_c^{*T} S_c(Z_c) + \epsilon_c \\
\hat{\Upsilon}(t) &= \hat{W}_c^T S_c(Z_c)
\end{aligned}$$
(29)

where $Z_c = \xi$, and other denotations follow NN denotations in Section 2.2. An ideal approximation is achieved if the following error is eliminated:

$$E_c \triangleq \frac{1}{2} (c - \hat{W}_c^I \dot{S}_c)^2 \tag{30}$$

Therefore, the updating law for the critic network is designed using the gradient descent method, as below:

$$\hat{W}_{c} = -\sigma_{c} \frac{\partial E_{c}}{\partial \hat{W}_{c}} = \sigma_{c} (c - \hat{W}_{c}^{T} \dot{S}_{c}) \dot{S}_{c}$$
(31)

where $\sigma_c > 0$ is the learning rate for the critic network.

Second, we introduce an action network to achieve the control objective discussed in Section 2.1. Define $e = x_0 - x_d$ as the tracking error, and the corresponding Lyapunov function candidate is $V_1 = \frac{1}{2}e^T e$. Its time derivative is

$$= e^{T} \dot{e}$$
$$= e^{T} (\dot{x}_{o} - \dot{x}_{d} - K_{1} e + K_{1} e)$$

where K_1 is a positive definite matrix. By defining $\dot{x}_r = \dot{x}_d - K_1 e$ and $e_v = \dot{x}_o - \dot{x}_r$, we have

$$\dot{V}_1 = -e^T K_1 e + e^T e_v \tag{33}$$

Considering the system dynamics (22) and another Lyapunov function candidate $V_2 = \frac{1}{2} e_v^T M e_v$, we have

$$\begin{split} \dot{V}_{2} &= \frac{1}{2} e_{\nu}^{T} \dot{M} e_{\nu} + e_{\nu}^{T} M \dot{e}_{\nu} \\ &= \frac{1}{2} e_{\nu}^{T} \dot{M} e_{\nu} + e_{\nu}^{T} (-C \dot{x}_{o} - G + u - M \ddot{x}_{r}) \\ &= e_{\nu}^{T} (-M \ddot{x}_{r} - C \dot{x}_{r} - G + u) \end{split}$$
(34)

where Property 5 is applied. It is trivial to design an ideal control $u^* = M\ddot{x}_r + C\dot{x}_r + G - e - K_2 e_v$, where K_2 is a positive definite matrix. However, since M, C and G are unknown, an action network is introduced to approximate the unknown parts of control input, as follows:

$$M\ddot{x}_r + C\dot{x}_r + G = W_a^{*T} S_a(Z_a) + \epsilon_a \tag{35}$$

where $Z_a = [q_i, \dot{q}_i, x_o, \dot{x}_o, \dot{x}_r, \ddot{x}_r]$. Then, the ideal control input becomes

$$u^* = W_a^{*T} S_a(Z_a) + \epsilon_a - e - K_2 e_v \tag{36}$$

and the actual control is designed as

$$u = \hat{W}_{a}^{T} S_{a}(Z_{a}) - e - K_{2} e_{\nu}$$
(37)

Considering a Lyapunov function candidate for both e and e_v , i.e. $V = V_1 + V_2$, we have

$$\dot{V} = \dot{V}_1 + \dot{V}_2 = -e^T K_1 e - e^T_v K_2 e_v + e^T_v (\tilde{W}_a^I S_a(Z_a) - \epsilon_a)$$
(38)

where $\tilde{W}_a = \hat{W}_a - W_a^*$ is the approximation error of NN weights. Since the objective of updating law of \tilde{W}_a is to minimize the approximation error \tilde{W}_a itself and the estimated cost function \hat{Y} , we define an error variable $e_a = \sum_{i=1}^{m} \tilde{W}_{a,i}^{i} S_a + k_Y \hat{Y}$, where $\tilde{W}_{a,i}$ is the *i*-th column of \tilde{W}_a and k_γ is a positive scalar. Again, using the gradient descent method, we obtain the updating law of action network as below:

$$\hat{W}_{a,i} = -\sigma_a(\hat{W}_{a,i}^I S_a + k_Y \hat{Y}) S_a \tag{39}$$

where σ_a is a designed learning rate for the action network.

3.3. Stability analysis

Consider a Lyapunov function candidate as below:

$$V = V_{1} + V_{2} + V_{c} + V_{a}$$
(40)
where $V_{c} = \frac{1}{2} \tilde{W}_{c}^{T} \tilde{W}_{c}$ and $V_{a} = \frac{1}{2} e_{a}^{T} e_{a}$. Its time derivative is
 $\dot{V} = \dot{V}_{1} + \dot{V}_{2} + \dot{V}_{c} + \dot{V}_{a}$

$$= -e^{T} K_{1} e - e_{v}^{T} K_{2} e_{v} + e_{v}^{T} (\tilde{W}_{a}^{T} S_{a} - \epsilon_{a}) + \tilde{W}_{c}^{T} \dot{\tilde{W}}_{c} + e_{a}^{T} \dot{e}_{a}$$

$$= -e^{T} K_{1} e - e_{v}^{T} K_{2} e_{v} + e_{v}^{T} (\tilde{W}_{a}^{T} S_{a} - \epsilon_{a})$$

$$+ \tilde{W}_{c}^{T} \dot{\tilde{W}}_{c} + e_{a}^{T} \left(\sum_{i=1}^{m} \dot{W}_{a,i}^{T} \frac{\partial e_{a}}{\partial \hat{W}_{a,i}} \right)$$

$$= -e^{T} K_{1} e - e_{v}^{T} K_{2} e_{v} + e_{v}^{T} (\tilde{W}_{a}^{T} S_{a} - \epsilon_{a})$$

$$+ \tilde{W}_{c}^{T} \dot{\tilde{W}}_{c} + e_{a} \left(\sum_{i=1}^{m} \dot{W}_{a,i}^{T} \right) S_{a}$$
(41)

(32)

(40)

Considering the updating law for the action network, i.e., Eq. (39), we have

$$\begin{split} \dot{V} &= -e^{T}K_{1}e - e^{T}_{\nu}K_{2}e_{\nu} + e^{T}_{\nu}(\tilde{W}_{a}^{T}S_{a} - \epsilon_{a}) + \tilde{W}_{c}^{T}\tilde{W}_{c} \\ &- \sigma_{a}S_{a}^{T}S_{a}e_{a}\sum_{i=1}^{m}(\hat{W}_{a,i}^{T}S_{a} + k_{Y}\hat{Y}) \\ &= -e^{T}K_{1}e - e^{T}_{\nu}K_{2}e_{\nu} + e^{T}_{\nu}\tilde{W}_{a}^{T}S_{a} - e^{T}_{\nu}\epsilon_{a} + \tilde{W}_{c}^{T}\dot{\tilde{W}}_{c} \\ &- \sigma_{a}S_{a}^{T}S_{a}e_{a}\sum_{i=1}^{m}(W_{a,i}^{*T}S_{a} + e_{a}) \\ &= -e^{T}K_{1}e - e^{T}_{\nu}K_{2}e_{\nu} + e^{T}_{\nu}\tilde{W}_{a}^{T}S_{a} - e^{T}_{\nu}\epsilon_{a} + \tilde{W}_{c}^{T}\dot{\tilde{W}}_{c} - \sigma_{a}S_{a}^{T}S_{a}e_{a}^{2} \\ &- \sigma_{a}S_{a}^{T}S_{a}e_{a}\sum_{i=1}^{m}W_{a,i}^{*T}S_{a} \end{split}$$

$$(42)$$

Considering the updating law for the critic network, i.e., Eq. (31), we have

$$\begin{split} \dot{V} &= -e^{T}K_{1}e - e^{T}_{v}K_{2}e_{v} + e^{T}_{v}\tilde{W}^{T}_{a}S_{a} - e^{T}_{v}\epsilon_{a} + \sigma_{c}\tilde{W}^{T}_{c}(c - \hat{W}^{T}_{c}\dot{S}_{c})\dot{S}_{c} \\ &- \sigma_{a}S^{T}_{a}S_{a}e^{2}_{a} - \sigma_{a}S^{T}_{a}S_{a}e_{a}\sum_{i=1}^{m}W^{*T}_{a,i}S_{a} \\ &= -e^{T}K_{1}e - e^{T}_{v}K_{2}e_{v} + e^{T}_{v}\tilde{W}^{T}_{a}S_{a} - e^{T}_{v}\epsilon_{a} + \sigma_{c}\tilde{W}^{T}_{c}(W^{*T}_{c}\dot{S}_{c} + \dot{\epsilon}_{c} - \hat{W}^{T}_{c}\dot{S}_{c})\dot{S}_{c} \\ &- \sigma_{a}S^{T}_{a}S_{a}e^{2}_{a} - \sigma_{a}S^{T}_{a}S_{a}e_{a}\sum_{i=1}^{m}W^{*T}_{a,i}S_{a} \\ &= -e^{T}K_{1}e - e^{T}_{v}K_{2}e_{v} + e^{T}_{v}\tilde{W}^{T}_{a}S_{a} - e^{T}_{v}\epsilon_{a} - \sigma_{c}\tilde{W}^{T}_{c}(\tilde{W}^{T}_{c}\dot{S}_{c} + \dot{\epsilon}_{c})\dot{S}_{c} \\ &- \sigma_{a}S^{T}_{a}S_{a}e^{2}_{a} - \sigma_{a}S^{T}_{a}S_{a}e_{a}\sum_{i=1}^{m}W^{*T}_{a,i}S_{a} \\ &\leq -e^{T}K_{1}e - e^{T}_{v}K_{2}e_{v} + e^{T}_{v}\tilde{W}^{T}_{a}S_{a} - e^{T}_{v}\epsilon_{a} - \frac{1}{2}\sigma_{c}\dot{S}^{T}_{c}\dot{S}_{c}\tilde{W}^{T}_{c}\tilde{W}_{c} + \frac{\sigma_{c}\dot{\epsilon}_{c}^{2}}{2} \\ &- \sigma_{a}S^{T}_{a}S_{a}e^{2}_{a} - \sigma_{a}S^{T}_{a}S_{a}e_{a}\sum_{i=1}^{m}W^{*T}_{a,i}S_{a} \end{split}$$

$$\tag{43}$$

Substituting inequalities

$$-e_{v}^{T}\epsilon_{a} \leq \frac{\|e_{v}\|^{2}}{2} + \frac{\epsilon_{a}^{2}}{2}$$

$$-S_{a}^{T}S_{a}e_{a}\sum_{i=1}^{m}W_{a,i}^{*T}S_{a} \leq \frac{S_{a}^{T}S_{a}e_{a}^{2}}{2} + \frac{\|\sum_{i=1}^{m}W_{a,i}^{*T}S_{a}\|^{2}}{2} \leq \frac{e_{a}^{2}}{2} + \|W_{a}^{*}\|^{2}$$

$$e_{v}^{T}\tilde{W}_{a}^{T}S_{a} \leq \frac{\|e_{v}\|^{2}}{2} + \frac{\|\tilde{W}_{a}^{T}S_{a}\|^{2}}{2}$$

$$\leq \frac{\|e_{v}\|^{2}}{2} + e_{a}^{2} + k_{Y}^{2}\tilde{Y}^{2}$$

$$\leq \frac{\|e_{v}\|^{2}}{2} + e_{a}^{2} + \frac{k_{Y}^{2}\|W_{c}^{*}\|^{2}}{2} + \frac{k_{Y}^{2}\|\tilde{W}_{c}\|^{2}}{2}$$

$$(44)$$

to the above inequality leads to

$$\begin{split} \dot{V} &\leq -e_{1}^{T}K_{1}e - e_{v}^{T}K_{2}e_{v} + \frac{\|e_{v}\|^{2}}{2} + e_{a}^{2} + \frac{k_{Y}^{2}\|W_{c}^{*}\|^{2}}{2} + \frac{k_{Y}^{2}\|\tilde{W}_{c}\|^{2}}{2} \\ &+ \frac{\|e_{v}\|^{2}}{2} + \frac{\epsilon_{a}^{2}}{2} - \frac{1}{2}\sigma_{c}\dot{S}_{c}^{T}\dot{S}_{c}\tilde{W}_{c}^{T}\tilde{W}_{c} + \frac{\sigma_{c}\dot{\epsilon}_{c}^{2}}{2} \\ &- \sigma_{a}S_{a}^{T}S_{a}e_{a}^{2} + \frac{\sigma_{a}e_{a}^{2}}{2} + \sigma_{a}\|W_{a}^{*}\|^{2} \\ &\leq -e_{1}^{T}K_{1}e - e_{v}^{T}(K_{2} - I)e_{v} - \frac{\sigma_{c}\dot{S}_{c}^{T}\dot{S}_{c} - k_{Y}^{2}}{2}\tilde{W}_{c}^{T}\tilde{W}_{c} \\ &- \left(\sigma_{a}S_{a}^{T}S_{a} - \frac{\sigma_{a} + 2}{2}\right)e_{a}^{2} + \frac{k_{Y}^{2}\|W_{c}^{*}\|^{2}}{2} \\ &+ \frac{\epsilon_{a}^{2}}{2} + \frac{\sigma_{c}\dot{\epsilon}_{c}^{2}}{2} + \sigma_{a}\|W_{a}^{*}\|^{2} \end{split}$$

$$(45)$$

In accordance with the definition of $V = V_1 + V_2 + V_c + V_a$ with $V_1 = \frac{1}{2}e^T e$, $V_2 = \frac{1}{2}e^T_v M e_v$, $V_c = \frac{1}{2}\tilde{W}_c^T \tilde{W}_c$ and $V_a = \frac{1}{2}e^T_a e_a$, we have $\dot{V} \leq -\rho V + \kappa$ (46)

where

$$\rho = \min\left\{2K_1, 2\lambda_{M\min}(K_2 - l), \sigma_c\beta_{S_c} - k_Y^2, 2\left(\sigma_a\beta_{S_a} - \frac{\sigma_a + 2}{2}\right)\right\}$$
$$\kappa = \frac{k_Y^2\beta_c^2}{2} + \frac{\varepsilon_a^2}{2} + \frac{\sigma_c\varepsilon_c^2}{2} + \sigma_a\beta_a^2 \tag{47}$$

where ε_a , ε_c , β_c , and β_a denote the upper bounds of ε_a , $\dot{\varepsilon}_c$, W_c^* , and W_a^* , respectively. In addition, $\beta_{S_c} \leq \dot{S}_c^T \dot{S}_c$ and $\beta_{S_a} \leq S_a^T S_a$.

According to Lemma 1, if the following conditions are satisfied:

$$K_2 - I > 0$$

$$\sigma_c \beta_{S_c} - k_Y^2 > 0$$

$$\sigma_a \beta_{S_a} - \frac{\sigma_a + 2}{2} > 0$$
(48)

then, all the closed-loop signals, including e, e_{ν} , \tilde{W}_c and e_a , will remain semi-globally uniformly ultimately bounded. For completeness, multiplying $\dot{V} = -\rho V + \kappa$ by $e^{\rho t}$, we can obtain

$$\frac{d}{dt}(e^{\rho t}V) \le \kappa e^{\rho t} \tag{49}$$

By integrating it, we can obtain

$$V \le \left(V(0) - \frac{\kappa}{\rho}\right) \kappa e^{-\rho t} + \frac{\kappa}{\rho} \le V(0) + \frac{\kappa}{\rho}$$
(50)

Therefore, signals e, e_v , \tilde{W}_c and e_a remain in the compact set $\Omega_1 := \{\chi \mid \|\chi\| \le \mu_r\}$ and finally they will converge to the convergence compact set $\Omega_2 := \{\chi \mid \|\chi\| \le \mu_c\}$, where

$$\mu_r = \sqrt{2\left(V(0) + \frac{\kappa}{\rho}\right)}, \quad \mu_c = \sqrt{\frac{2\kappa}{\rho}}$$
(51)

From definitions of ρ and κ in Eq. (47), we find that sizes of Ω_1 and Ω_2 can be adjusted by choosing different values of design parameters, e.g., K_1 , K_2 , σ_a , and σ_c . They can be made very small but other effects of improper selection of design parameters should also be considered.

4. Simulation study

In this section, simulation study is conducted to verify the validity of the proposed method. In particular, two 2-degrees-of-freedom (2-DoF) planar manipulators coordinate to move an object together along a desired trajectory. These two manipulators have same parameters, which are given in Table 1, where m_i , l_i , and l_{zi} , i=1, 2, represent mass, length, and moment of inertia about the axis that comes out of the page passing through the center of mass, respectively. The object under consideration is a square with length l=0.1 m, mass $m_o = 0.1$ kg, and moment of inertia $I_o = 0.1$ kg m². The desired trajectory of the mass center of the object is $x_d = [0.1 \cos (t)0.1 \sin (t)0]^T$, which indicates that no rotation is expected while the translation motion is a circle. It is

Table 1	
Parameters of each robot manipul	ator.

Parameter	Description	Value
$m_1 \\ m_2 \\ l_1 \\ l_2 \\ l_{z1}$	Mass of link 1 Mass of link 2 Length of link 1 Length of link 2 Moment of inertia of link 1	2.00 kg 0.85 kg 0.30 m 0.30 m 0.05 kg m ²
I _{z2}	Moment of inertia of link 2	0.02 kg m ²

Fig. 1. Trajectories of the mass center of the object (top and middle: translation; bottom: rotation).

Fig. 2. Three components of control input.

generated by Eq. (25) with

$$U = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad Y = 0.1I$$
(52)

The initial position and velocity of the object are $x_0(0) = [0 \ 0 \ 0]^T$ and $\dot{x}_0(0) = [0 \ 0 \ 0]^T$, respectively.

Denote joint angles of the first and second robot manipulators as q_1 and q_2 , and q_3 and q_4 , respectively. Correspondingly, positions of end-effectors of the first and second robot manipulators are x_1 and x_2 , and x_3 and x_4 , respectively. Then, we have the kinematic relationship from the joint space of each robot manipulator to its corresponding Cartesian space, as below:

$$x_1 = d_1 + l_1 \cos q_1 + l_2 \cos (q_1 + q_2)$$

$$x_2 = l_1 \sin q_1 + l_2 \sin (q_1 + q_2)$$

$$x_{3} = d_{2} + l_{1} \cos q_{3} + l_{2} \cos (q_{3} + q_{4})$$

$$x_{4} = l_{1} \sin q_{3} + l_{2} \sin (q_{3} + q_{4})$$
(53)

where $[d_1, 0]^T$ and $[d_2, 0]^T$ are positions of bases of two robot manipulators. For the kinematic relationship from the end-effector of each robot manipulator to the mass center of the object, we have

$$x_{o,1} = \frac{l}{2} \cos \theta + x_1$$

$$x_{o,2} = \frac{l}{2} \sin \theta + x_2$$

$$x_{o,1} = -\frac{l}{2} \cos \theta + x_3$$

$$x_{o,2} = -\frac{l}{2} \sin \theta + x_4$$
(54)

Fig. 3. Norms of estimates of NN weights.

Fig. 4. Instant cost function.

Therefore, the Jacobian matrices from the joint space of each robot manipulator to its corresponding Cartesian space are

$$J_{r,1}(q) = \begin{bmatrix} -l_1 \sin q_1 - l_2 \sin (q_1 + q_2) & -l_2 \sin (q_1 + q_2) \\ l_1 \cos q_1 + l_2 \cos (q_1 + q_2) & l_2 \cos (q_1 + q_2) \end{bmatrix}$$

$$J_{r,2}(q) = \begin{bmatrix} -l_1 \sin q_3 - l_2 \sin (q_3 + q_4) & -l_2 \sin (q_3 + q_4) \\ l_1 \cos q_3 + l_2 \cos (q_3 + q_4) & l_2 \cos (q_3 + q_4) \end{bmatrix}$$
(55)

The Jacobian matrices from the end-effector of each robot manipulator to the mass center of the object are

$$J_{1}(x_{o}) = \begin{bmatrix} 1 & 0 & \frac{l}{2}\sin\theta \\ 0 & 1 & -\frac{l}{2}\cos\theta \end{bmatrix}$$

$$J_{2}(x_{o}) = \begin{bmatrix} 1 & 0 & -\frac{l}{2}\sin\theta \\ 0 & 1 & \frac{l}{2}\cos\theta \end{bmatrix}$$
(56)

For detailed dynamic models of robot manipulators, readers may refer to [25]. For the critic network, centers are evenly distributed in [-1, 1], the variance is 50, and the corresponding number of NN nodes is 2^{10} . For the actor network, centers are also evenly distributed in [-1, 1], the variance is 100, and the number of NN nodes is 2^{16} . The initial NN weights are all set as zeros. Other parameters are set as $\sigma_a = \sigma_c = 0.1$, $K_1 = 10I$, $K_2 = 5I$, and $k_Y = 0.2$. A white Gaussian noise of power 0 dBW is added into the control input.

Simulation results are shown in Figs. 1–4. Fig. 1 demonstrates that the trajectory of the mass center of the object tracks the desired trajectory. Fig. 2 illustrates that the control input is guaranteed to be bounded and it becomes very small when the trajectory tracking in Fig. 1 is achieved. As discussed in the Introduction, since the control input is penalized in the proposed method, it leads to compliance of each robot manipulator with others when there exists disagreement. Besides, norms of estimates of NN weights for critic and actor networks are shown in Fig. 3, which are found to be bounded and eventually converge to certain constants. Correspondingly, from Fig. 4, it is found that the instant cost function defined in Eq. (7) reduces significantly with respect to time. These results well demonstrate that the proposed control achieves the tracking performance of the object manipulated by multi-robots, while the compliance of each individual robot manipulator is also guaranteed.

5. Conclusion

In this paper, we have investigated the control problem for multi-robots coordinated manipulation. By considering both the dynamics of the object and robot manipulators, we have obtained a combined system model which is feasible for the control design. To address the issue of unknown dynamics, we have employed reinforcement learning and developed two neural networks for the control design. Lyapunov's direct method has been used for the performance analysis of the closed-loop system under the proposed control. Two-robots co-manipulation has been considered in simulation to verify the effectiveness of the proposed control in that trajectory tracking of the object is achieved and the control effort of each manipulator is minimized.
